Siemens 549-214

01 Identify the active field-panel connection

1. Identify whether the point block is reached through the MEC expansion connection or P1 FLN. Match the physical module to its database objects and distinguish the HOA-ready base from fitted override accessories. Record each sensor and actuator assignment before making changes to the controller database.

2. Do not carry a database mapping across to a differently connected module simply because the enclosure looks the same.

Acceptance observation	The field-panel connection and analog-point assignments are unambiguous.
Evidence to retain	Connection map and approved baseline
Release boundary	Use the applicable APOGEE MEC / P1 FLN instructions and the approved application acceptance criteria.

02 Prepare enclosure and wiring segregation

1. Review the enclosure arrangement for the actual building-control application. Energy-management surface mounting and smoke-control enclosure requirements are different. For the applicable CE arrangement, inspect the metal enclosure, cable entries and minimum IP20 protection, then check wiring-class separation before restoring power.

2. If the enclosure or segregation is unsuitable, correct the assembly rather than treating the bare module as proof of compliance.

Acceptance observation	The completed assembly matches its intended application and enclosure boundary.
Evidence to retain	Isolation and supply assessment
Release boundary	Use the applicable APOGEE MEC / P1 FLN instructions and the approved application acceptance criteria.

03 Match analog points to controller objects

1. Restore the identified analog terminals without interchanging input and output circuits. Compare the connected sensor or receiver signal type with the commissioned point configuration. Check field-device supply arrangements independently of communication health. Keep actuator motion controlled while the output path is being reconnected.

2. A network response does not establish that a particular analog circuit has power, correct polarity or the intended destination.

Acceptance observation	Every physical point retains the correct signal direction and configured object.
Evidence to retain	Restored interface and configuration
Release boundary	Use the applicable APOGEE MEC / P1 FLN instructions and the approved application acceptance criteria.

04 Trace inputs and commands independently

1. Apply a controlled input stimulus and compare the field measurement with the corresponding database value. Test outputs in the opposite direction: issue an authorized command, measure the resulting signal and observe the receiver. Keep these two test paths separate so a mapping error is not hidden by a common label.

2. If a value appears at the wrong database object, reconcile the point map before adjusting scaling or replacing the field device.

Acceptance observation	Input acquisition and output delivery agree with their respective physical circuits.
Evidence to retain	Measured response and diagnostic state
Release boundary	Use the applicable APOGEE MEC / P1 FLN instructions and the approved application acceptance criteria.

549-214

05 Restore normal building-control authority

1. Restore automatic authority only after the receiving equipment follows the correct command direction and limit behavior. Check any actually fitted manual override independently, then return it to the approved operating position. Retain the connection type, enclosure assessment and final point map with the building-control records.

2. A successful input test alone cannot release an actuator circuit that has not been checked from command to final response.

Technical basis: Siemens Point Expansion Modules, 586-148-05; Power MEC for BACnet Networks.
